Buoyancy - High School Physics and AP Physics Online

Explanation: The buoyant force is the weight of the volume of water displaced by the immersed object. Since the rock is completely submerged, the buoyant force is the weight of water with the same volume as the rock. Despite the rock sinking, there is still a buoyant force; it is just less than the weight of the rock.

This is something difficult to visualize. But here is how to get there: The force of water above the object is given by rho*g*h, and the buoyant force underneath the object is equal to the (pressure at the bottom of the object)* (surface area of the bottom of the object). Let's look a little closer at that surface area.

Buoyancy is an easy concept to understand about pressure in a fluid. In a fluid may be a gas or a liquid, pressure increases with depth. Learn the buoyancy formula here.

Buoyancy is an upward force that a fluid exerts on an object that is immersed in it. It causes things to float or else results in an apparent loss of weight of a body when it sinks in the fluid. This is called the buoyant force. The important physics law dealing with buoyancy is called Archimedes' Principle.
