The ability of seeds to germinate readily when conditions are suitable for successful growth and the ability to avoid germination at inappropriate times, through the maintenance of dormancy, can also be controlled by endogenous chemicals. 19 Seed of some fleshy fruits, such as strawberry and tomato, will not germinate in the fruit because of the presence of chemical germination inhibitors. 22 Some desert plant seeds germinate only after a heavy rain, the seedlings assured adequate moisture ...

Black's textbook Seeds: physiology of development and germination maintains the standards that they have established in their previous collaborations. Their two-volume workPhysiobgy and biochemistry of seeds in relation to germination (1978 and 1982) was acclaimed for its com-prehensive coverage, critical analysis of the primary

Seeds: physiology of development and germination. The second edition of this book includes new information and concepts in areas of the subject where considerable advances have been made since the publication of the first edition in 1985. While some sections have been altered relatively little, others covering seed development, effects of abscisic acid and gibberellins on gene expression and some aspects of dormancy have been extensively...

Unlike bryophyte and fern spores (which are haploid cells dependent on moisture for rapid development of gametophytes), seeds contain a diploid embryo that will germinate into a sporophyte. It has storage tissue to sustain growth and a protective coat give seeds their superior evolutionary advantage.

Biology of seed development and germination physiology

Seeds are highly dehydrated and naturally require water before germination. The first phase of seed germination is water imbibition till critical level of water is attained. Once the imbibition is completed, seeds begin to germinate and seedling emerges out. Radicle or root penetrates the seed coat and is followed by shoot emergence.

Physiology of Seed Germination - Biology Discussion

Physiological, Biochemical and Other Changes Accompanying Seed Germination. Physiology of Seed Germination: All the viable seeds which have overcome dormancy (if any) either naturally or artificially will readily germinate under suitable environmental conditions necessary for seed germination i.e., water, O₂, temperature and in some cases light. Such seeds which just wait for suitable environmental conditions to germinate are said to be 'quiescent'.

In response to enormous recent advances, particularly in molecular biology, the authors have revised their warmly received work. This new edition includes updates on seed development, gene expression, dormancy, and other subjects. It will serve as the field's standard textbook and reference source for many years to come.

a preceding period of dormancy (often). The seeds of many temperate-climate angiosperms will germinate only after a prolonged period of cold. An inhibitor within the seed (probably abscisic acid - ABA) is gradually broken down at low temperatures until finally there is not enough to prevent germination when other conditions become favorable.

ABA-deficient mutant 'seeds are a useful demonstration that ABA can prevent germination and impose at least an equivalent to dormancy during seed development. An inter- esting secondary characteristic of developing seeds of the sit mutant of tomato is that they produce a thinner testa.

Molecular Biology of Barley Seed Germination Gibberellic acid (GA), which is one of the plant hormones, is produced by the scutellum (cotyledon) of the embryo stimulates the production of amylase by the aleurone layer amylase hydrolyzes starch to simple sugars absorbed by scutellum and translocated to embryo for growth.
