7.6k Downloads In this chapter, we develop a dynamic model for a rigid vehicle having forward, lateral, yaw, and roll velocities. The model of a rollable rigid vehicle is more exact and more effective compared to the rigid vehicle planar model. Using this model, we are able to analyze the roll behavior of a vehicle as well as its maneuvering.

Large displacements and rotations are accounted for in this nonlinear model so that it can be used for the study of roll dynamics well beyond the limits of wheel lift-off. The model is used to illustrate some of the dynamic phenomena in vehicle rollover, especially the interactive coupling between the roll and the vertical modes of motion.

~~Roll Dynamics of Commercial Vehicles: Vehicle System ...~~

In this paper, a three-degree-of-freedom model is employed for computer simulation to determine the relationship between the planar and roll motions of a large-size vehicle, so that the roll motion could be eventually predicted to prevent the vehicle from going dynamically unstable.

Vehicle dynamics simulation helps the development of a control algorithm to compensate vehicle body dynamics also during these extreme maneuvers, without oscillations. Active Roll Control can be adopted to improve handling by varying the distribution between the anti-roll torques generated by front and rear stabilizer bars.

Two key variables that are difficult to measure and play a critical role in the rollover index are found to be the roll angle and the height of the center of gravity of the vehicle. Algorithms are developed for real-time estimation of these variables. The algorithms investigated include a sensor fusion algorithm and a nonlinear dynamic observer.
